

Is there an association between alcohol consumption frequency and suicidal ideation among adolescents?

Data & Variables

Dataset: YRBS 2007

Exposure Variable

Current Alcohol Use (Past 30 Days)

Outcome Variable

- 1 = Suicidal ideation (Yes)
- 0 = No suicidal ideation

Sample size: n = 12,630

Method

- Descriptive Analysis
- Logistic Regression
- Odds Ratio (OR)

Key Results

Suicidal ideation prevalence increased from 10.1% (0 days) to 45.8% (all 30 days).

Logistic Regression

- Coefficient = 0.2805
- p-value < 0.001
- Odds Ratio (OR) = 1.32

Conclusion

Higher alcohol consumption frequency was significantly associated with suicidal ideation among adolescents ($p < 0.001$). Each increase in drinking category increased the odds of suicidal ideation by 32% (OR = 1.32).
